

Why Ring starts near the middle: reference semantics, not swapped X/Y coordinates

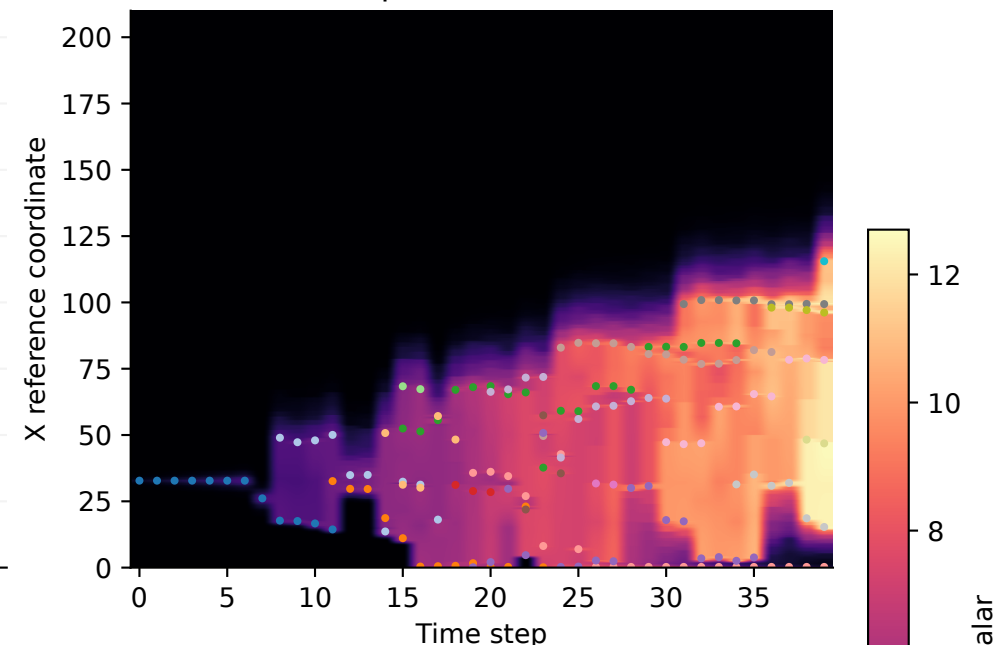

Ring t = 0: two different reference points

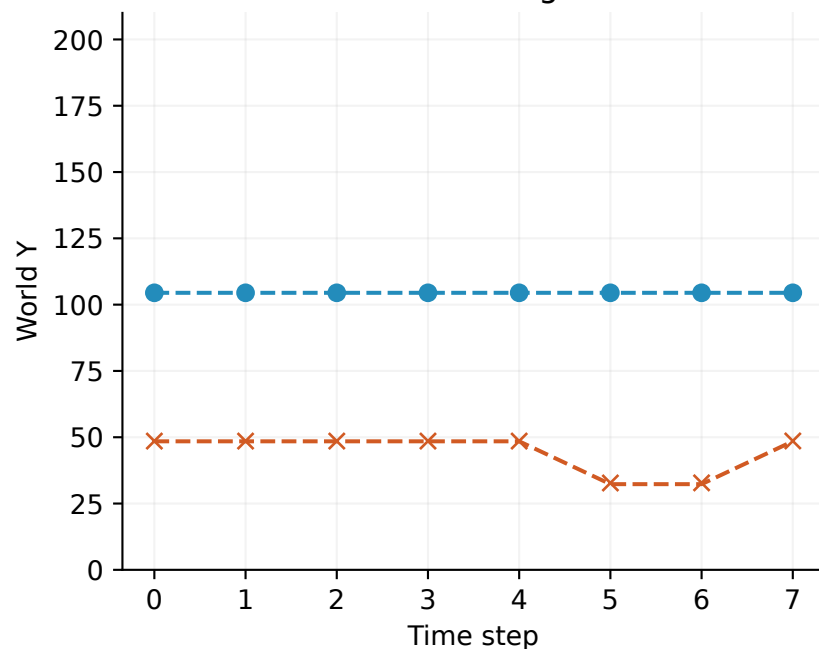

X reference: first eight frames

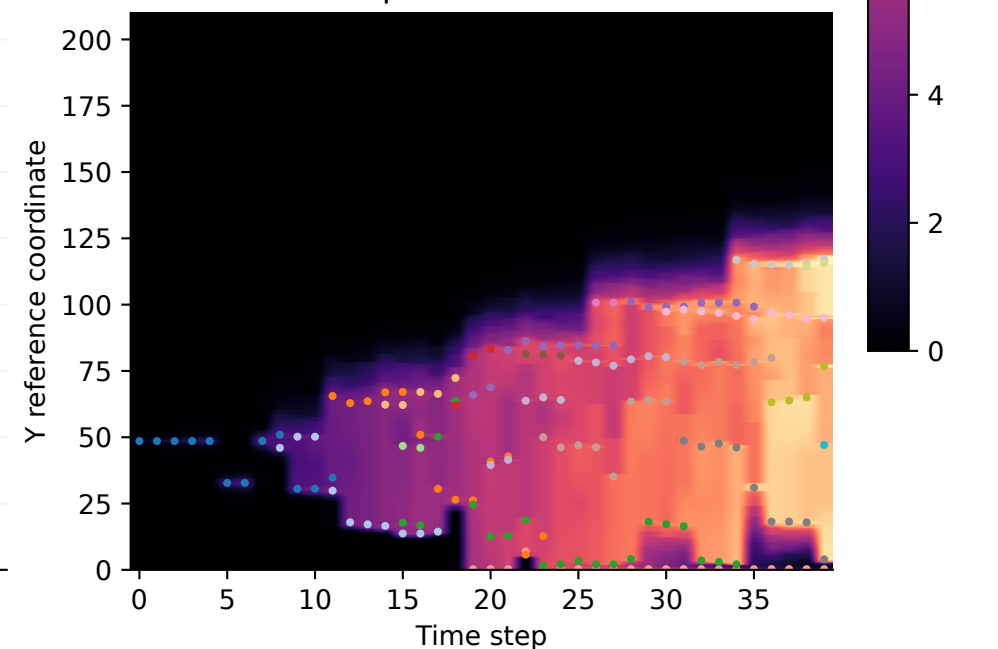

Dual peak-reference: X

Y reference: first eight frames

Dual peak-reference: Y

First leaf support: 195 / 196 grid samples

Centroid: average of support coordinates.
Peak: location of the leaf scalar extremum.

Both variants keep identical:
hierarchy, absolute widths, canvas,
geometry distances and solver parameters.

Two axes recover the chosen reference,
not the full scalar field or ring center.

Peak switching can cause discrete jumps;
constraints can still displace anchors.
